

Egg Donation for In Vitro Fertilization

In vitro fertilization is known as one of the best solutions for correcting the problem of infertility; be it with man or woman. Females who are not able to conceive due to their incapability to produce fertile eggs need the help of other women who can donate their eggs. Nowadays, there are women who are readily available for egg donation due to monetary reasons. These women usually charge a good amount of money from the helpless couples in return for their eggs.

There are also some women who out of generosity donate their eggs. This process is known as third party reproduction in which the help of an outsider is sought to have a baby. The world has become selfish and in the midst of it, there are some nice people as well who feel sad seeing others in pitiable condition.

Egg donation has become a common phenomenon in the present time, as more and more couples are having a tough time conceiving a child. In the process of egg donation, the donator allows the doctor to extract her ova or the eggs so that it can give a new ray of hope to a childless couple.

Before discussing further about the egg donation process for performing the in vitro fertilization surgery, let us first try to find out who can actually donate the eggs. It has been seen that different clinics have different requirements for donation of eggs. But, the common criteria are that the donator should be in the age group of 18-30. The donator should not be into the habit of smoking or drinking and drugs are a total no for the donor. This is due to the fact that it can have an adverse effect on the body.

Since the child usually gets the features of its parents, it is preferred to find a donor having good features or to put in other words one should look for a donor sharing compatible features with the spouse of the patient. For example, if the parents are tall and fair, then it is better to find a woman having fair complexion and a good height. Therefore, it is necessary to pay attention to the physical attributes of the egg donor. This in turn will ensure that it does not show clearly that it is someone else's child.

It is a mandatory condition in most of the clinics to check properly if the egg donor is suffering from any chronic disease such as cancer and AIDS, because it is likely that the child might develop the same problem due to genetic reasons. Before undergoing the in vitro fertilization procedure, egg donation is given due consideration and special emphasis is on ensuring that the eggs obtained are safe for mixing with the sperms of the male. This is recommended to every woman who goes for in vitro fertilization treatment.
